Drug Summary

Elvitegravir-cobicistat-tenofovir disoproxil fumarate (DF)-emtricitabine is a single-tablet regimen used predominantly for initial therapy. Elvitegravir-cobicistat-tenofovir DF-emtricitabine is generally well tolerated, but has some limitations, including gastrointestinal side effects caused by cobicistat and risk of renal toxicity and bone mineral density loss secondary to tenofovir DF. Initiation of elvitegravir-cobicistat-tenofovir DF-emtricitabine is not recommended in patients with an estimated creatinine clearance less than 70 mL/min. The cobicistat component also has significant drug interactions with certain other antiretroviral medications and with many non-HIV medications. The single tablet regimen elvitegravir-cobicistat-tenofovir DF-emtricitabine differs from the similar newer fixed dose combination elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine only by the tenofovir component. In many clinical settings, elvitegravir-cobicistat-tenofovir DF-emtricitabine is being replaced by elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine due to potential for reduced long term renal and bone adverse effects with the latter drug.

Guidelines for use in Antiretroviral-Naïve Patients

In the October 17, 2017 version of the HHS Guidelines for the Use of Antiretroviral Agents in Adults and Adolescents Living with HIV, elvitegravir-cobicistat-tenofovir DF-emtricitabine is designated as listed below for treatment-naïve patients:

- Recommended Initial Regimens for Most People with HIV
  - Elvitegravir-cobicistat-tenofovir DF-emtricitabine (AI)

- Recommended Initial Regimens in Certain Clinical Situations
Key Clinical Trials

In treatment-naïve adults, elvitegravir-cobicistat-tenofovir DF-emtricitabine showed equivalent rates of virologic suppression when compared with efavirenz-tenofovir DF-emtricitabine [GS-236-0102 (Study 102)] and with atazanavir plus ritonavir plus tenofovir-DF-emtricitabine [GS-236-0103 (Study 103)]. In treatment-naïve adult women, elvitegravir-cobicistat-tenofovir DF-emtricitabine demonstrated superior virologic suppression rates, largely driven by better tolerability, when compared with atazanavir plus ritonavir plus tenofovir-DF-emtricitabine [WAVES]. Elvitegravir-cobicistat-tenofovir DF-emtricitabine and elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine were also compared as initial therapy, and study participants had equivalent virologic suppression rates, though the tenofovir alafenamide-containing regimen was favorable in terms of renal and bone adverse effects [GS-292-0104/GS-292-0111 (Study 104/111)]. Studies have also shown that patients with no history of virologic failure or HIV drug resistance can switch from a virologically suppressive regimen of tenofovir DF-emtricitabine plus an NNRTI [STRATEGY-NNRTI], tenofovir DF-emtricitabine plus a boosted protease inhibitor [STRATEGY-PI], or tenofovir DF-emtricitabine plus raltegravir, to elvitegravir-cobicistat-tenofovir DF-emtricitabine and maintain virologic suppression [GS-236-0123].

Adverse Effects

Elvitegravir-cobicistat-tenofovir DF-emtricitabine can cause fatigue, headache, malaise, nausea, and diarrhea. The emtricitabine and elvitegravir components of the regimen generally cause few side effects. The gastrointestinal side effects, which are among the most common adverse events with this regimen, are likely caused by the cobicistat component. Tenofovir DF can cause decreased bone mineral density and renal toxicity, including proximal tubular injury. Elvitegravir-cobicistat-tenofovir DF-emtricitabine should be discontinued if the patient’s estimated creatinine clearance decreases to less than 50 mL/min. Because elvitegravir-cobicistat-tenofovir DF-emtricitabine contains two medications (tenofovir DF and emtricitabine) that have activity against hepatitis B virus, discontinuation of elvitegravir-cobicistat-tenofovir DF-emtricitabine in patients with chronic hepatitis B infection can potentially cause a severe exacerbation of hepatitis B.

Use In Pregnancy

In the HHS Perinatal Guidelines section Recommendations for Use of Antiretroviral Drugs During Pregnancy (last updated October 19, 2017), elvitegravir-cobicistat-tenofovir DF-emtricitabine is designated in the category of Not Recommended for Initial ART in Pregnancy, because of concerns of virologic breakthrough due to lowered levels of elvitegravir and cobicistat in the second and third trimesters of pregnancy.
