Drug Summary

Tenofovir alafenamide-emtricitabine is a two-NRTI component of multiple approved first-line treatment options, including the single-tablet regimens elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine and rilpivirine-tenofovir alafenamide-emtricitabine. Tenofovir alafenamide is a prodrug of tenofovir that is hydrolyzed to tenofovir in plasma, and then phosphorylated to the active compound within cells. When compared with tenofovir disoproxil fumarate (DF), tenofovir alafenamide generates approximately 90% lower tenofovir plasma levels, which correlates with an improved safety profile. Studies have shown that tenofovir alafenamide, when compared with tenofovir DF, causes less adverse impact on markers of renal proximal tubule wasting and bone mineral density, but also less lipid lowering. At this time, data on the long-term clinical impact related to differences in these parameters are lacking. Tenofovir alafenamide can be used in the setting of mild-moderate renal insufficiency (creatinine clearance as low as 30 mL/min). It is FDA approved for the treatment of hepatitis B. At this time, data are lacking to support the use of tenofovir alafenamide for preexposure prophylaxis, postexposure prophylaxis, or for use in pregnant women with HIV infection. There are no food restrictions

Guidelines for use in Antiretroviral-Naïve Patients

In the October 17, 2017 version of the HHS Guidelines for the Use of Antiretroviral Agents in Adults and Adolescents Living with HIV, tenofovir alafenamide-emtricitabine is designated as listed below for treatment-naïve patients:

Recommended Initial Regimens for Most People with HIV

- Dolutegravir plus tenofovir alafenamide-emtricitabine (AI)
- Elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine (AI)
- Raltegravir plus tenofovir alafenamide-emtricitabine (AII)
Recommended Initial Regimens in Certain Clinical Situations

- Darunavir plus ritonavir plus tenofovir alafenamide-emtricitabine (AI)
- Darunavir-cobicistat plus tenofovir alafenamide-emtricitabine (AII)
- Atazanavir plus ritonavir plus tenofovir alafenamide-emtricitabine (BI)
- Atazanavir-cobicistat plus tenofovir alafenamide-emtricitabine (BI)
- Efavirenz plus tenofovir alafenamide-emtricitabine (BII)
- Rilpivirine-tenofovir alafenamide-emtricitabine (BI)—if HIV RNA less than 100,000 copies/mL and CD4 count greater than 200 cells/mm³

Key Clinical Trials

The combination tenofovir alafenamide-emtricitabine has been compared to tenofovir DF-emtricitabine in studies of initial therapy and in switch studies. In antiretroviral-naïve subjects, elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine demonstrated non-inferior virologic efficacy as compared to elvitegravir-cobicistat-tenofovir DF-emtricitabine [GS-292-0104/GS-292-0111 (Study 104/111)]. In virologically suppressed patients, a switch to elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine from antiretroviral therapy that included tenofovir DF-emtricitabine plus elvitegravir-cobicistat, atazanavir plus ritonavir, or efavirenz found the tenofovir alafenamide-based regimen to be equally effective as elvitegravir-cobicistat-tenofovir DF-emtricitabine and superior to the regimens that included boosted atazanavir or efavirenz [GS-292-0109 (Study 109)]. A switch from other first-line therapy to elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine in the setting of mild-moderate renal insufficiency (creatinine clearance 30 to 69 mL/min) also maintained virologic suppression and led to improvements in markers of renal proximal tubule wasting and bone mineral density [GS-292-0112 (Study 112)]. Similarly, a switch from tenofovir DF-emtricitabine to tenofovir alafenamide-emtricitabine demonstrated equivalent efficacy with improvement in renal and bone biomarkers [GS-311-1089]. In a study of treatment-experienced individuals with multiclass drug resistance who met certain criteria and who were taking suppressive salvage regimens, simplification to elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine plus darunavir led to statistically higher rates of treatment efficacy as compared to continuing current therapy [GS-292-0119 (Study 119)]. In an open-label, non-randomized study, participants with HIV-hepatitis B coinfection (most of whom had suppressed HBV DNA level) switched antiretroviral therapy to elvitegravir-cobicistat-tenofovir alafenamide-emtricitabine; a high rate of treatment success in terms of maintaining HIV virologic suppression and maintaining or achieving hepatitis B suppression occurred [GS-292-1249 (Study 1249)].

Adverse Effects

The emtricitabine component of tenofovir alafenamide-emtricitabine infrequently causes significant short-term or long-term adverse effects. Hyperpigmentation of the palms and soles has been reported with emtricitabine and the risk is higher in persons with darker pigmented skin. The primary advantage of tenofovir alafenamide over tenofovir DF is reduced adverse effects related to proximal tubule toxicity and bone mineral density loss; the long-term clinical significance of these differences is not yet known. A switch from tenofovir DF to tenofovir alafenamide leads to a mild increase in serum lipid markers, though the clinical significance is unclear. Tenofovir alafenamide-emtricitabine can cause nonspecific symptoms such as fatigue, headache, malaise, nausea, and other gastrointestinal symptoms.
Use In Pregnancy

In the HHS Perinatal Guidelines section Recommendations for Use of Antiretroviral Drugs During Pregnancy (last updated October 19, 2017), tenofovir alafenamide-emtricitabine is designated in the category Insufficient Data in Pregnancy to Recommend Routine Use in Initial Regimens for ART-Naive Women.

- For additional information regarding the safety and toxicity of tenofovir alafenamide and emtricitabine in pregnancy see the HHS Perinatal Guidelines summaries on Tenofovir alafenamide and Emtricitabine.

Resistance

For a listing of the most common clinically significant mutations associated with tenofovir alafenamide-emtricitabine (TAF-FTC) resistance, see the NRTI Resistance Notes on the Stanford University HIV Drug Resistance Database.

Note that both tenofovir alafenamide and tenofovir disoproxil fumarate are converted to tenofovir disphophate, the active form of the drug. Thus, resistance mutations for tenofovir alafenamide (TAF) and tenofovir disoproxil fumarate (TDF) are the same.

Key Drug Interactions

For complete information on tenofovir alafenamide-emtricitabine-related drug interactions, see the Drug Interactions section in the Tenofovir alafenamide-Emtricitabine (Descovy) Prescribing Information.

No Clinical Trials Available

We do not currently have any clinical trials on file for this drug.
